Multilevel Meta-Analysis Tutorial

Hu, M., Koh, P.S., Soh, X.C., Hartanto, A., Majeed, N.M.

Introduction

The following script is designed to perform a multilevel meta-analysis using the metafor and lmerTest packages in R.

The analysis is based on data from Hartanto et al. (2024) and focuses on the relationship between smartphone presence and cognitive functions. The original paper can be found here: https://doi.org/10.1037/tmb0000123.

The script includes steps for data preparation, effect size calculation, overall effect size computation, forest plot generation, tests for publication bias, and moderation analysis.

The script is structured to be run in RStudio, and it includes comments to guide users through each step of the process.

Setting Up

This section sets up the working environment, installs necessary packages, loads the required libraries, and reads in the data.

If the metafor and lmerTest packages are not already installed, use the install.packages() function to install them.

Explanation of the Code

- The setwd() function sets the working directory to the location of the script, ensuring that all file paths are relative to the script's location.
- The library() function loads the metafor and lmerTest packages.
- The options() function is used to adjust the display settings, specifically to disable scientific notation and set the number of digits displayed.
- The read.csv() function reads in the data from a CSV file named "SPC.csv", which contains the data drawn from Hartanto et al. (2024).
- A new column named "ID" is created in the data frame to assign unique IDs to each row of data.

```
### Set Up ------
# R version 4.5.0

# Set working directory to that of script's current location
setwd(dirname(rstudioapi::getActiveDocumentContext()$path))

# Load packages
library(metafor) # version 4.8-0
```

Loading required package: Matrix

```
## Loading required package: metadat
## Loading required package: numDeriv
##
## Loading the 'metafor' package (version 4.8-0). For an
## introduction to the package please type: help(metafor)
library(lmerTest) # version 3.1-3
## Loading required package: lme4
##
## Attaching package: 'lmerTest'
## The following object is masked from 'package:lme4':
##
##
       lmer

# Display settings (to disable scientific notation)
options(scipen = 9999, digits = 4)
# Read in data drawn from Hartanto et al. 2024
multilevelmeta_raw = read.csv("SPC.csv")
# Create new column with unique IDs
multilevelmeta_raw$ID = 1:nrow(multilevelmeta_raw)
```

Prepare Data

This section prepares the data for analysis by computing effect sizes for each study and organizing the data frame.

The multimeta_raw data frame does not include pre-computed effect sizes for each study. However, the data frame does include the necessary information to compute effect sizes, such as sample sizes, means, and standard deviations for each group (presence of smartphones and absence of smartphones). The escalc() function from metafor package can use this information to compute the effect sizes directly.

For more information on the escalc() function, refer to ?escalc in R.

- The measure argument specifies the type of effect size to be calculated, which in this case is "SMD" (Standardized Mean Difference). In the metafor package, specifying "SMD" computes Hedge's g by default.
- The n1i and n2i arguments specify the columns for the sample sizes of each group.
- The m1i and m2i arguments specify the columns for the means of each group.
- The sd1i and sd2i arguments specify the columns for the standard deviations of each group.
- Afterwards, the escalc() function computes the effect sizes (yi) and their corresponding sampling variances (vi) for each study.

- The multilevelmeta\$publication variable is converted to a factor with specified levels to ensure that the publication types (e.g., journal articles, thesis/dissertation, conference) are ordered correctly in the forest plot.
- The c() function combines the types of publication into a character vector.
- The multilevelmeta data frame is then sorted by the type of publication (e.g., journal articles, thesis/dissertation, conference) and corresponding effect sizes to facilitate clearer visualization in the forest plot. Do note that the comma before the closing square bracket is required, as it indicates that we are keeping the columns while reordering the rows.

```
### Prepare Data -----
# Compute effect sizes for each study
multilevelmeta = escalc(
       # Type of effect size measure
       measure = "SMD",
       # Columns for sample size of each group
       n1i = n_p,
      n2i = n_a,
       # Columns for means of each group
       m1i = cog M p,
       m2i = cog_M_a,
       # Columns for standard deviation of each group
       sd1i = cog_SD_p,
       sd2i = cog_SD_a,
       # Specify data.frame that the information will be extracted from
       data = multilevelmeta_raw
)
# Convert publication type to a factor with specified levels
multilevelmeta$publication = factor(
      multilevelmeta$publication,
       levels = c("Journal article", "Thesis/dissertation", "Conference")
)
# Order the data frame based on publication type and effect sizes (yi)
multilevelmeta = multilevelmeta[order(multilevelmeta$publication, multilevelmeta$yi), ]
```

Computing the Overall Effect Size

This section estimates the overall effect size using the rma.mv() function from the metafor package.

Specifically, we demonstrate the difference in calculating the overall effect size using a traditional meta-analysis approach versus a multilevel meta-analysis approach.

The traditional meta-analysis approach is not recommended for multilevel data, as it does not account for the nested structure of the data (i.e., studies nested within labs).

The multilevel meta-analysis approach is more appropriate for this type of data, as it accounts for the hierarchical structure and allows for the inclusion of random effects.

Explanation of the Multilevel Meta-Analysis Code

- The rma.mv() function is used to compute the overall effect size, accounting for the nested structure of the data.
- The random argument specifies the random effects structure, where ~ 1 | lab_id / ID indicates that random intercepts are included for both the lab and individual studies, accounting for the nested structure of the data.
- The yi and vi arguments specify the effect size estimates and their corresponding sampling variances, respectively.
- The data argument specifies the data frame containing the effect size estimates and variances.
- The summary() function is used to display the results of the meta-analysis, including the overall effect size estimate and its confidence interval.

```
### Compute Overall Effect Size -----
# Using multilevel code
# The code below is the recommended approach for multilevel meta-analysis
mlmmetaresults = rma.mv(
       # Effect size estimates
      yi = yi,
       # Sampling variances
       V = vi,
       # Include random effects for grouping variable (i.e., lab)
       random = ~ 1 | lab_id / ID,
       # Specify where to get the data from
       data = multilevelmeta
)
# summary function used to provide detailed results of the meta-analysis
summary(mlmmetaresults)

Forest Plot

This section generates a forest plot to visually represent the effect sizes and confidence intervals for each study included in the meta-analysis.

The forest plot is created using the forest() function from the metafor package.

The plot includes the following features:

- Arrangement of studies by effect sizes
- Sample size information for both presence of smartphones and absence of smartphones groups
- Custom headers for the plot
- Custom labels for the studies

After running this code, the forest plot will appear as shown on page 8 of this handbook.

Explanation of the Code

• The forest() function is used to create the forest plot, and the mlmmetaresults object contains the results of the meta-analysis.

- The order argument specifies the arrangement of studies, with "obs" indicating that the studies should be arranged by effect sizes. To organise by column, replace "obs" with the specific column in the data frame.
- The ylim argument sets the y-axis limits for the plot.
- The ilab argument is used to add extra columns of information to the forest plot beyond just the effect sizes. Here, we are adding sample size data for both the presence of smartphones and absence of smartphones groups.
- The cbind() function combines multiple columns side-by-side. In this case, the sample sizes of the groups (n_p and n_a) will appear side-by-side in the forest plot.
- The ilab.xpos argument specifies where the sample size columns appear horizontally on the plot. The negative values position the columns on the left side of the plot, just after the study labels.
- The slab argument is used to label each effect size with its respective study.
- The paste() function creates the label by combining the "author" and "year_published" columns. The sep argument specifies the separator between the columns, which is set to "," in this case. Hence, the label will be in the format "Author(s), Year Published" (e.g., "Smith, 2020").
- The xlim argument sets the x-axis limits for the plot.
- The alim argument sets the confidence interval limits, and the steps argument determines the number
 of intervals in the x-axis.
- The efac argument controls the size of the diamond shapes that represent the effect sizes in the plot.
- The header argument is set to FALSE to allow for manual specification of headers.
- The xlab argument specifies the confidence interval label for the forest plot, in this case, "Hedge's g".
- The text() function is used to manually include text within the plot, such as the "Author(s) Year" header and specific sample size column headers.
- The x and y arguments in the text() function adjust the position of the headers, with the x argument specifying the horizontal arrangement of the columns and the y argument specifying the vertical arrangement of the columns.
- The font argument adjusts the font size.

```
# Label studies on the forest plot
       slab = paste(author, year_published, sep = ", "),
       # Add x-axis limits
       xlim = c(-5, 3),
       # Add confidence interval limits
       # Adjust intervals based on the number of steps
       alim = c(-2, 2),
       steps = 9,
       # Change size of effect size polygons
       efac = 0.3,
       # Show (TRUE) or hide (FALSE) default headers
       # Hide when we want to manually specify our own headers
       header = FALSE,
       # Add label for confidence interval, in this case, "Hedge's g"
       xlab = "Hedge's g"
)
# For the following lines of code,
# Use text function to manually include text within the plot
# Add "Author(s) Year" header
text(x = -4.6, y = 139, "Author(s) Year", font = 2)
# Add "Sample Size" header
text(x = -2.8, y = 139.6, "Sample Size", font = 2)
# Add specific sample size column headers, "Presence" and "Absence"
\# x = -3 for for presence of smartphones
# x = -2.55 for absence of smartphones
# y = 139  for  both
text(c(x = -3, x = -2.55), y = 139, c("Presence", "Absence"), font = 2)
# Add "q [95% CI]" header
text(x = 2.7, y = 139, "g [95\% CI]", font = 2)
```

Optional: Saving the Forest Plot as a Separate File

Saving the forest plot as a PDF file allows for easy sharing and presentation, and allows adjustment to the plot's dimensions.

Explanation of the Code

- To save the forest plot as a PDF file, the plotting code can be enclosed within pdf() and dev.off() functions:
- The pdf() function starts the graphics device driver to create PDF files, and the file argument specifies the name of the file.
- The width and height arguments adjust the dimensions of the PDF file.
- Following the pdf() function, the same code used to create the forest plot is repeated to generate the plot within the PDF file. The graphical output will be directed to the specified PDF file instead of the RStudio plotting window.
- The dev.off() function is used to close the graphics device and finalise the plot as a saved file.

```
### Saving the Forest Plot as a Separate File (Optional) -----
# Save the forest plot as a PDF file
# Name the pdf file of the forest plot
pdf(file = "mlmforestplot.pdf", width = 15, height = 40)
# Same forest plot code as above
forest(
      mlmmetaresults,
      order = "obs",
      ylim = c(-3, 140),
      ilab = cbind(n_p, n_a),
       ilab.xpos = c(-3, -2.55),
       slab = paste(author, year_published, sep = ", "),
       xlim = c(-5, 3),
       alim = c(-2, 2),
       steps = 9,
      efac = 0.3,
      header = FALSE,
      xlab = "Hedge's g"
)
text(x = -4.6, y = 139, "Author(s) Year", font = 2)
text(x = -2.8, y = 139.6, "Sample Size", font = 2)
text(c(x = -3, x = -2.55), y = 139, c("Presence", "Absence"), font = 2)
text(x = 2.7, y = 139, "g [95\% CI]", font = 2)
# Close the forest plot and finalise it as a saved file
dev.off()
```

pdf ## 2

Tests for Publication Bias

This section performs tests for publication bias, including a funnel plot and Egger's test.

For multilevel meta-analysis, we do not recommend conducting a rank correlation test as it is prone to Type 1 error.

Researchers may refer to this article by Fernández-Castilla et al. (2019) on a detailed discussion of the limitations of rank correlation tests in multilevel meta-analysis, as well as an overview on other publication bias tests: https://doi.org/10.1080/00220973.2019.1582470:

Funnel Plot

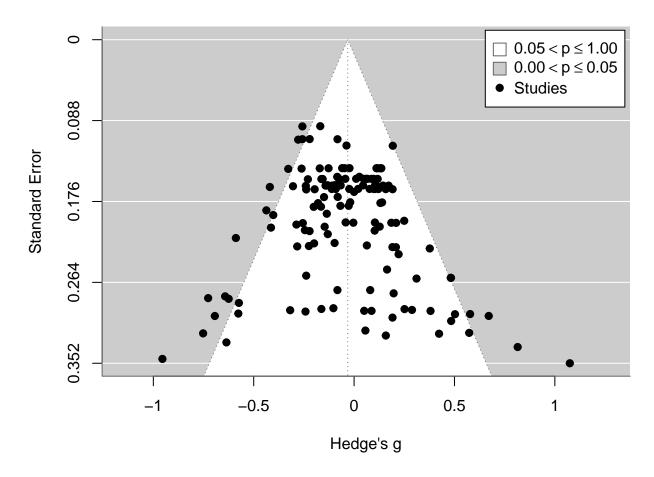

The funnel plot visually represents the distribution of effect sizes and their standard errors, allowing for the identification of potential publication bias.

After running this code, the funnel plot will appear as shown on page 11 of this handbook.

- The par() function is used to adjust the margins of the funnel plot, with the mar argument specifying the bottom, left, top, and right margins.
- The funnel() function is used to create the funnel plot, and the mlmmetaresults object contains the results of the meta-analysis.
- The legend argument specifies whether to include a legend in the plot. TRUE indicates that a legend should be included, FALSE indicates that it should not.
- The xlab argument specifies the confidence interval label for the funnel plot, in this case, "Hedge's g".

```
### Tests for Publication Bias -----
# Funnel Plot #

# Adjust margins of the funnel plot
# Set the bottom, left, top, and right margins
par(mar = c(4, 4, 0.3, 1))
# Create the funnel plot
funnel(mlmmetaresults, legend = TRUE, xlab = "Hedge's g")
```

Optional: Saving the Funnel Plot as a Separate File

Saving the funnel plot as a PDF file allows for easy sharing and presentation, and allows adjustment to the plot's dimensions.

- To save the funnel plot as a PDF file, the plotting code can be enclosed within pdf() and dev.off() functions:
- The pdf() function starts the graphics device driver to create PDF files, and the file function specifies the name of the file.
- The width and height arguments adjust the dimensions of the PDF file.
- Following the pdf() function, the same code used to create the funnel plot is repeated to generate the plot within the PDF file. The graphical output will be directed to the specified PDF file instead of the RStudio plotting window.
- The dev.off() function is used to close the graphics device and finalize the plot as a saved file.

```
### Saving the Funnel Plot as a Separate File (Optional) -----
# Funnel Plot #

# Save the funnel plot as a PDF file
# Name the pdf file of the funnel plot
# Adjust the width and height of the pdf file
```

```
pdf(file = "mlmfunnelplot.pdf", width = 8, height = 5)

# Same funnel plot code as above
par(mar = c(4, 4, 0.3, 1))
funnel(mlmmetaresults, legend = TRUE, xlab = "Hedge's g")

# Close the funnel plot and finalise it as a saved file
dev.off()

## pdf
## pdf
## 2
```

Egger's Test

The Egger's test is a statistical test that quantifies the degree of asymmetry in the funnel plot, providing a more formal assessment of publication bias.

- The multilevelmeta\$sei_corrected variable is created to store the corrected standard error for each effect size, calculated using the formula $\sqrt{\frac{(n_p+n_a)}{(n_p\cdot n_a)}}$. Using Egger' test (unadjusted) on SMDs results in inflated Type 1 error as SMD and SE are not independent. Hence, use corrected formula for SE.
- The lmer() function is used to fit a linear mixed-effects model, where the effect size weighted by the corrected standard error is predicted by the intercept and the inverse of the corrected standard error. metafor::rma.mv does not have a weights argument, and metafor::regtest does not support rma.mv objects. For three (or more) level meta-analysis, use lmerTest::lmer instead.
- The I(yi / sei_corrected) expression indicates that the effect size (yi) is divided by the corrected standard error (sei_corrected), which is used to weight the effect sizes in the model.
- The I(1 / sei_corrected) expression indicates that the inverse of the corrected standard error is included in the model as a predictor.
- The 1 | lab_id expression indicates that random intercepts are included for each lab, accounting for the nested structure of the data.
- The data argument specifies the dataset to be used for the analysis.
- The summary() function provides the results of the Egger's test, including the slope estimate and its significance.

```
# Estimate of interest is the intercept
summary(correlation = FALSE)
```

```

Moderation Analysis

This section performs moderation analysis to explore the influence of categorical and continuous moderators on the effect sizes.

For continuous moderators, use meta-regression. Specifically, the modsfunction specifies the moderator variable (for continuous moderators).

For categorical moderators, use subgroup analysis. Specifically, the **subset** argument is used to specify the subset of data for categorical moderators, allowing for separate analyses for each category.

- The rma.mv() function is used to perform the moderation analysis.
- The yi and vi arguments specify the effect size estimates and their corresponding sampling variances, respectively.
- The random argument specifies the random effects structure, where ~ 1 | lab_id / ID indicates that random intercepts are included for both the lab and individual studies, accounting for the nested structure of the data.
- The mods argument specifies the moderator variable (for continuous moderators).
- The subset argument is used to specify the subset of data for categorical moderators, allowing for separate analyses for each category.
- The method argument specifies the method used to estimate heterogeneity, in this case, "REML" (Restricted Maximum Likelihood).

- The data argument specifies the dataset to be used for the analysis.
- The summary() function is used to display the results of the meta-analysis, including the overall effect size estimate and its confidence interval.

Note that if convergence issues arise, the control argument can be used to address it. Researchers may also refer more to the metafor package documentation for more information on how to address convergence issues.

```

Forest Plot of Moderators

This section generates a forest plot that includes moderators to visually represent the effect sizes and confidence intervals for each study included in the meta-analysis.

The forest plot includes the following features:

- Arrangement of studies by effect sizes and types of moderators
- Sample size information for both presence of smartphones and absence of smartphones groups
- Custom headers for the plot
- Custom labels for the studies
- Summary effect sizes for each moderator

After running this code, the forest plot with moderators will appear as shown on page 20 of this handbook.

- The forest() function is used to create the forest plot, and the mlmmetaresults object contains the results of the meta-analysis.
- The rows argument specifies the arrangement of studies by publication type, and in ascending order of effect sizes per publication type.
- The ylim argument sets the y-axis limits for the plot.

- The ilab argument is used to add extra columns of information to the forest plot beyond just the effect sizes. Here, we are adding sample size data for both the presence of smartphones and absence of smartphones groups.
- The cbind() function combines multiple columns side-by-side. In this case, the sample sizes of the groups (n_p and n_a) will appear side-by-side in the forest plot.
- The ilab.xpos argument specifies where the sample size columns appear horizontally on the plot. The negative values position the columns on the left side of the plot, just after the study labels.
- The slab argument is used to label each effect size with its respective study.
- The paste() function creates the label by combining the "author" and "year_published" columns. The sep argument specifies the separator between the columns, which is set to "," in this case. Hence, the label will be in the format "Author(s), Year" (e.g., "Smith, 2020").
- The xlim argument sets the x-axis limits for the plot.
- The alim argument sets the confidence interval limits, and the steps argument determines the number of intervals in the x-axis.
- The efac argument controls the size of the diamond shapes that represent the effect sizes in the plot.
- The header argument is set to FALSE to allow for manual specification of headers.
- The xlab argument specifies the label for the confidence interval, in this case, "Hedge's g".
- The text() function is used to manually include text within the plot, such as the "Author(s) Year" header and specific sample size column headers.
- The x and y arguments in the text() function adjust the position of the headers, with x argument specifying the horizontal arrangement of the columns and the y specifying the vertical arrangement of the columns.
- The post argument specifies the position of the text relative to the specified coordinates.
- The font argument adjusts the font size.
- The rma.mv() function is used to perform moderation analysis for each publication type, with the subset argument specifying the subset of data for each category.
- The rest.j, res.t, and res.c variables store the results of the moderation analysis for journal articles, thesis/dissertations, and conference papers, respectively.
- The random argument specifies the random effects structure, where ~ 1 | lab_id / ID indicates that random intercepts are included for both the lab and individual studies, accounting for the nested structure of the data.
- The subset argument is used to specify the subset of data for categorical moderators, allowing for separate analyses for each category.
- The addpoly() function is used to add summary effect sizes for each of the moderators, with the row argument specifying the position of the summary in the plot.

```
# - Conference: Rows 3 to 2
       # The arrangement must consider spacing and must end at row 2
       rows = c(143:79, 75:7, 3:2),

Optional: Saving the Forest Plot of Moderators as a Separate File

Saving the forest plot of moderators as a PDF file allows for easy sharing and presentation, and allows adjustment to the plot's dimensions.

- To save the forest plot of moderators as a PDF file, the plotting code can be enclosed within pdf() and dev.off() functions:
- The pdf() function starts the graphics device driver to create PDF files, and the file argument specifies the name of the file.
- The width and height arguments adjust the dimensions of the PDF file.
- Following the pdf() function, the same code used to create the forest plot of moderators is repeated to generate the plot within the PDF file. The graphical output will be directed to the specified PDF file instead of the RStudio plotting window.
- The dev.off() function is used to close the graphics device and finalise the plot as a saved file.

```
### Forest Plot of Moderators -----
# Save the forest plot as a PDF file
# Name the pdf file of the forest plot
# Adjust the width and height of the pdf file
pdf(file = "mlmforestplotwithmoderators.pdf", width = 15, height = 45)
# Same forest plot code as above
forest(
       mlmmetaresults,
       rows = c(143:79, 75:7, 3:2),
